mel's move: corn sweat summer

what is corn sweat?

Corn Sweat describes the process through which corn releases moisture into the atmosphere. Water is released into the air both from the soil and from the inside of the cornstalk. One acre of corn can release up to 5,000 gallons of water in 1-2 days. Five acres would release enough water to fill an average swimming pool!

Created by Mel Morgan, 2025 (Including route data, and heat index calculations)
